CS330: Operating Systems

Filesystem: caching and consistency

Recap: file system

- File system is an important OS subsystem
 - Provides abstractions like files and directories
 - Hides the complexity of underlying storage devices

Recap: file system organization

- File systems maintain several meta-data structures like super blocks, inodes, directory entries to provide a file system abstractions like files, directories
- How to search/lookup files/directories in a given path?
- Read the content of the root inode and search the next level dir using the name and find out its inode number
- Read the inode to check permissions and repeat the process
- Inode contains the index structures to deduce the disk block address given an logical offset

- Accessing data and metadata from disk impacts performance
- Many file operations require multiple block access

- Accessing data and metadata from disk impacts performance
- Many file operations require multiple block access
- Examples:
 - Opening a file

```
fd = open("/home/user/test.c", O_RDWR);
```

- Accessing data and metadata from disk impacts performance
- Many file operations require multiple block access
- Examples:
 - Opening a file

```
fd = open("/home/user/test.c", O_RDWR);
```

Normal shell operations

```
/home/user$ ls
```

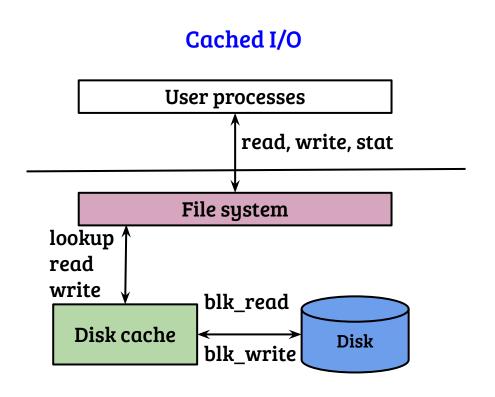

- Accessing data and metadata from disk impacts performance
- Many file operations require multiple block access
- Executables, configuration files, library etc. are accessed frequently
- Many directories containing executables, configuration files are also accessed very frequently. Metadata blocks storing inodes, indirect block pointers are also accessed frequently

/home/user\$ ls

- Accessing data and metadata from disk impacts performance
- Can we store frequently accessed disk data in memory?
 - What is the storage and lookup mechanism? Are the data and metadata caching mechanisms same?
 - Are there any complications because of caching?
 - How the cache managed? What should be the eviction policy?

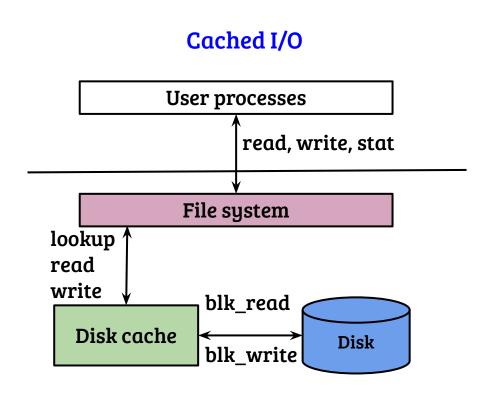

/home/user\$ ls

Block layer caching

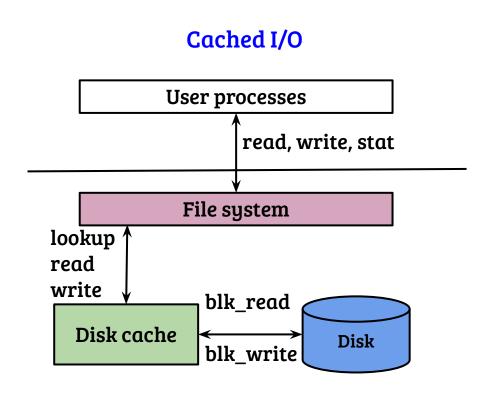

- Lookup memory cache using the block number as the key
- How does the scheme work for data and metadata?

Block layer caching

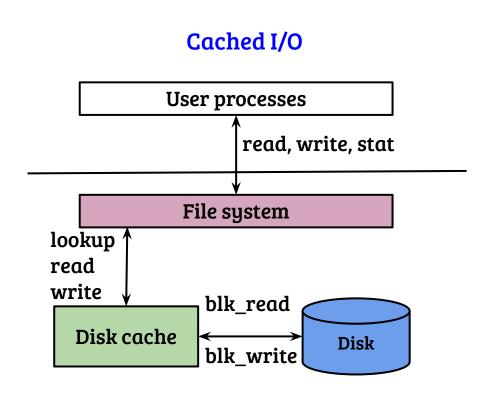

- Lookup memory cache using the block number as the key
- How does the scheme work for data and metadata?
- For data caching, file offset to block address mapping is required before using the cache

Block layer caching

- Lookup memory cache using the block number as the key
- How does the scheme work for data and metadata?
- For data caching, file offset to block address mapping is required before using the cache
- Works fine for metadata as they are addressed using block numbers

File layer caching (Linux page cache)

- Store and lookup memory cache using {inode number, file offset} as the key
- For data, index translation is not required for file access
- Metadata may not have a file association, should be handled differently (using a special inode may be!)

- Accessing data and metadata from disk impacts performance
- Can we store frequently accessed disk data in memory?
 - What is the storage and lookup mechanism? Are the data and metadata caching mechanisms same?
 - File layer caching is desirable as it avoids index accesses on hit, special mechanism required for metadata.
 - Are there any complications because of caching?
 - How the cache managed? What should be the eviction policy?

Caching and consistency

- Caching may result in inconsistency, but what type of consistency?

Caching and consistency

- Caching may result in inconsistency, but what type of consistency?
- System call level guarantees
 - Example-1: If a write() system call is successful, data must be written
 - Example-2: If a file creation is successful then, file is created.
 - Difficult to achieve with asynchronous I/O

Caching and consistency

- Caching may result in inconsistency, but what type of consistency?
- System call level guarantees
 - Example-1: If a write() system call is successful, data must be written
 - Example-2: If a file creation is successful then, file is created.
 - Difficult to achieve with asynchronous I/O
- Consistency w.r.t. file system invariants
 - Example-1: If a block is pointed to by an inode data pointers then,
 corresponding block bitmap must be set
 - Example-2: Directory entry contains an inode, inode must be valid
 - Possible, require special techniques

File system inconsistency: root causes

Update contents of disk blocks

Disk block caching (delayed write)

System crash (software, power failure)

Storage medium failure (sector(s) damaged)

 No consistency issues if user operation translates to read-only operations on the disk blocks

 Always keep in mind: device level atomicity guarantees
